## Vector and matrix algebra

#### Packages for this section

• This is (almost) all base R! We only need this for one thing later:

```
library(tidyverse)
```

#### **Vector addition**

Adds 2 to each element.

• Adding vectors:

```
u <- c(2, 3, 6, 5, 7)
v <- c(1, 8, 3, 2, 0)
u + v
```

```
[1] 3 11 9 7 7
```

• Elementwise addition. (Linear algebra: vector addition.)

#### Adding a number to a vector

• Define a vector, then "add 2" to it:

u

[1] 2 3 6 5 7

k <- 2 u + k

[1] 4 5 8 7 9

• adds 2 to each element of u.

## **Scalar multiplication**

As per linear algebra:

k

[1] 2

u

[1] 2 3 6 5 7

k \* u

[1] 4 6 12 10 14

• Each element of vector multiplied by 2.

## "Vector multiplication"

What about this?

u

[1] 2 3 6 5 7

V

[1] 1 8 3 2 0

```
u * v
```

#### [1] 2 24 18 10 0

Each element of u multiplied by *corresponding* element of v. Could be called elementwise multiplication.

(Don't confuse with "outer" or "vector" product from linear algebra, or indeed "inner" or "scalar" multiplication, for which the answer is a number.)

#### Combining different-length vectors

• No error here (you get a warning). What happens?

u

#### [1] 2 3 6 5 7

```
w \leftarrow c(1, 2)
u + w
```

#### [1] 3 5 7 7 8

- Add 1 to first element of u, add 2 to second.
- Go back to beginning of w to find something to add: add 1 to 3rd element of u, 2 to 4th element, 1 to 5th.

#### How R does this

- Keep re-using shorter vector until reach length of longer one.
- "Recycling".
- If the longer vector's length not a multiple of the shorter vector's length, get a warning (probably not what you want).
- Same idea is used when multiplying a vector by a number: the number keeps getting recycled.

#### **Matrices**

• Create matrix like this:

```
(A <- matrix(1:4, nrow = 2, ncol = 2))

[,1] [,2]
[1,] 1 3
[2,] 2 4
```

- First: stuff to make matrix from, then how many rows and columns.
- R goes down columns by default. To go along rows instead:

```
(B <- matrix(5:8, nrow = 2, ncol = 2, byrow = TRUE))

[,1] [,2]
[1,] 5 6
[2,] 7 8
```

• One of nrow and ncol enough, since R knows how many things in the matrix.

#### **Adding matrices**

What happens if you add two matrices?

Α

В

## **Adding matrices**

• Nothing surprising here. This is matrix addition as we and linear algebra know it.

## Multiplying matrices

• Now, what happens here?

Α

В

### Multiplying matrices?

- Not matrix multiplication (as per linear algebra).
- $\bullet\,$  Elementwise multiplication. Also called  ${\it Hadamard\ product}$  of A and B.

## Legit matrix multiplication

Like this:

Α [,1] [,2] [1,] 1 [2,] 2 4 В [,1] [,2] [1,] 5 [2,] 7 8 A %\*% B [,1] [,2] [1,] 26 30 [2,] 38 44

## Reading matrix from file

• The usual:

```
my_url <- "http://ritsokiguess.site/datafiles/m.txt"
M <- read_delim(my_url, " ", col_names = FALSE )
M

# A tibble: 3 x 2
    X1    X2
    <dbl> <dbl>
1    10    9
2    8    7
3    6    5
```

```
class(M)
```

```
[1] "spec_tbl_df" "tbl_df" "tbl" "data.frame"
```

#### but...

• except that M is not an R matrix, and thus this doesn't work:

```
v <- c(1, 3)
M %*% v
```

Error in M %\*% v: requires numeric/complex matrix/vector arguments

#### Making a genuine matrix

Do this first:

```
M <- as.matrix(M)
```

X1 X2

[1,] 10 9 [2,] 8 7

[3,] 6 5

v

[1] 1 3

and then all is good:

[,1]

[1,] 37

[2,] 29

[3,] 21

## Linear algebra stuff

• To solve system of equations Ax = w for x:

Α

```
[,1] [,2]
[1,] 1 3
[2,] 2 4
```

7

[1] 1 2

```
solve(A, w)
```

[1] 1 0

#### Matrix inverse

• To find the inverse of A:

Α

solve(A)

• You can check that the matrix inverse and equation solution are correct.

## Inner product

• Vectors in R are column vectors, so just do the matrix multiplication (t() is transpose):

```
a <- c(1, 2, 3)
b <- c(4, 5, 6)
t(a) %*% b
```

- Note that the answer is actually a  $1 \times 1$  matrix.
- Or as the sum of the elementwise multiplication:

```
sum(a * b)
```

[1] 32

#### Accessing parts of vector

• use square brackets and a number to get elements of a vector

b

[1] 4 5 6

b[2]

[1] 5

## Accessing parts of matrix

• use a row and column index to get an element of a matrix

Α

A[2,1]

#### [1] 2

• leave the row or column index empty to get whole row or column, eg.

A[1,]

[1] 1 3

## Eigenvalues and eigenvectors

• For a matrix A, these are scalars  $\lambda$  and vectors v that solve

$$Av = \lambda v$$

• In R, eigen gets these:

Α

## Eigenvalues and eigenvectors

е

```
eigen() decomposition

$values

[1] 5.3722813 -0.3722813
```

\$vectors

#### To check that the eigenvalues/vectors are correct

•  $\lambda_1 v_1$ : (scalar) multiply first eigenvalue by first eigenvector (in column)

```
e$values[1] * e$vectors[,1]

[1] -3.039462 -4.429794

• Av<sub>1</sub>: (matrix) multiply matrix by first eigenvector (in column)

A %*% e$vectors[,1]

[,1]
[1,] -3.039462
[2,] -4.429794

• These are (correctly) equal.
```

# A statistical application of eigenvalues

• The second one goes the same way.

• A negative correlation:

• cor gives the correlation matrix between each pair of variables (correlation between x and y is -0.988)

#### Eigenanalysis of correlation matrix

## eigen(v)

eigen() decomposition
\$values

[1] 1.98787834 0.01212166

#### \$vectors

[,1] [,2]

[1,] -0.7071068 -0.7071068

[2,] 0.7071068 -0.7071068

- first eigenvalue much bigger than second (second one near zero)
- two variables, but data nearly one-dimensional
- opposite signs in first eigenvector indicate that the one dimension is:
  - $\mathbf x$  small and  $\mathbf y$  large at one end,
  - x large and y small at the other.
