Tidying data

Tidying data

- Data rarely come to us as we want to use them.
- ▶ Before we can do analysis, typically have organizing to do.
- This is typical of ANOVA-type data, "wide format":

```
pig feed1 feed2 feed3 feed4

1 60.8 68.7 92.6 87.9

2 57.0 67.7 92.1 84.2

3 65.0 74.0 90.2 83.1

4 58.6 66.3 96.5 85.7

5 61.7 69.8 99.1 90.3
```

- ▶ 20 pigs randomly allocated to one of four feeds. At end of study, weight of each pig is recorded.
- Are any differences in mean weights among the feeds?
- Problem: want all weights in one column, with 2nd column labelling which feed. Untidy!

Tidy and untidy data (Wickham)

- Data set easier to deal with if:
 - each observation is one row
 - each variable is one column
 - each type of observation unit is one table
- Data arranged this way called "tidy"; otherwise called "untidy".
- For the pig data:
 - response variable is weight, but scattered over 4 columns, which are levels of a factor feed.
 - Want all the weights in one column, with a second column feed saying which feed that weight goes with.
 - Then we can run aov.

Packages for this section

library(tidyverse)

Reading in the pig data

```
my_url <- "http://ritsokiguess.site/datafiles/pigs1.txt"
pigs1 <- read_delim(my_url, " ")</pre>
pigs1
# A tibble: 5 \times 5
    pig feed1 feed2 feed3 feed4
  <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
      1 60.8 68.7 92.6 87.9
2
     2 57 67.7 92.1 84.2
3
     3 65 74 90.2 83.1
   4 58.6 66.3 96.5 85.7
4
5
     5 61.7 69.8 99.1 90.3
```

Making it longer

- ▶ We wanted all the weights in one column, labelled by which feed they went with.
- ► This is a very common reorganization, and the magic "verb" is pivot_longer:

```
# A tibble: 20 x 3
    pig feed weight
   <dbl> <chr> <dbl>
      1 feed1 60.8
      1 feed2 68.7
3
      1 feed3 92.6
4
      1 feed4 87.9
 5
      2 feed1 57
 6
      2 feed2 67.7
      2 feed3
                92.1
```

Alternatives

Any way of choosing the columns to pivot longer is good, eg:

```
# A tibble: 20 \times 3
    pig feed weight
   <dbl> <chr> <dbl>
       1 feed1 60.8
       1 feed2 68.7
3
       1 feed3 92.6
4
      1 feed4 87.9
 5
      2 feed1 57
6
                67.7
      2 feed2
 7
      2 feed3
                92.1
8
      2 feed4
                84.2
9
                65
      3 feed1
10
      3 feed2
                74
                90.2
11
      3 feed3
```

Comments

- pigs2 now in "long" format, ready for analysis.
- Anatomy of pivot_longer:
 - columns to combine
 - ▶ a name for column that will contain groups ("names")
 - ▶ a name for column that will contain measurements ("values")

Identifying the pigs

6

7

8

9

- Values in pig identify pigs within each group: pig 1 is four different pigs!
- Create unique pig IDs by gluing pig number onto feed:

```
pigs2 %>% mutate(pig_id=str_c(feed, "_", pig)) -> pigs2
pigs2
```

```
# A tibble: 20 x 4

pig feed weight pig_id

<dbl> <chr> <dbl> <chr> <dbl> <chr> 1 1 feed1 60.8 feed1_1
2 1 feed2 68.7 feed2_1
3 1 feed3 92.6 feed3_1
4 1 feed4 87.9 feed4_1
5 2 feed1 57 feed1 2
```

3 feed1

2 feed2 67.7 feed2 2

2 feed3 92.1 feed3 2

2 feed4 84.2 feed4 2

65

feed1 3

...and finally, the analysis

which is just what we saw before:

```
weight.1 <- aov(weight ~ feed, data = pigs2)
summary(weight.1)</pre>
```

```
Df Sum Sq Mean Sq F value Pr(>F)

feed 3 3521 1173.5 119.1 3.72e-11 ***

Residuals 16 158 9.8

---

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '
```

- The mean weights of pigs on the different feeds are definitely not all equal.
- So we run Tukey to see which ones differ (over).

Tukey

TukeyHSD(weight.1)

```
Tukey multiple comparisons of means 95% family-wise confidence level
```

Fit: aov(formula = weight ~ feed, data = pigs2)

\$feed

```
diff lwr upr p adj
feed2-feed1 8.68 3.001038 14.358962 0.0024000
feed3-feed1 33.48 27.801038 39.158962 0.0000000
feed4-feed1 25.62 19.941038 31.298962 0.0000000
feed3-feed2 24.80 19.121038 30.478962 0.0000000
feed4-feed2 16.94 11.261038 22.618962 0.0000013
feed4-feed3 -7.86 -13.538962 -2.181038 0.0055599
```

All of the feeds differ!

Mean weights by feed

To find the best and worst, get mean weight by feed group. I borrowed an idea from earlier to put the means in descending order:

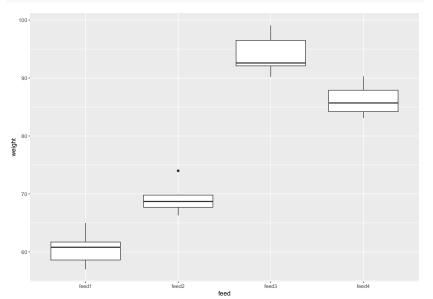

```
pigs2 %>%
  group_by(feed) %>%
  summarize(mean_weight = mean(weight))%>%
  arrange(desc(mean_weight))
```

```
# A tibble: 4 x 2
feed mean_weight
<chr> <dbl>
1 feed3 94.1
2 feed4 86.2
3 feed2 69.3
4 feed1 60.6
```

Feed 3 is best, feed 1 worst.

Should we have any concerns about the ANOVA?

ggplot(pigs2, aes(x = feed, y = weight)) + geom_boxplot()

Comments

- Feed 2 has an outlier
- But there are only 5 pigs in each group
- ▶ The conclusion is so clear that I am OK with this.

Tuberculosis

- ▶ The World Health Organization keeps track of number of cases of various diseases, eg. tuberculosis.
- Some data:

```
my_url <- "http://ritsokiguess.site/datafiles/tb.csv"
tb <- read_csv(my_url)</pre>
```

The data (randomly chosen rows)

```
tb %>% slice_sample(n = 10)
```

What we have

- Variables: country (abbreviated), year. Then number of cases for each gender and age group, eg. m1524 is males aged 15–24. Also mu and fu, where age is unknown.
- Lots of missings. Want to get rid of.
- Abbreviations here.

- Code for pivot_longer:
 - columns to make longer
 - column to contain the names (categorical)
 - column to contain the values (quantitative)
 - drop missings in the values

Results (some)

tb2

```
# A tibble: 35,750 x 4
  iso2 year genage freq
  <chr> <dbl> <chr> <dbl>
1 AD 1996 m014
2 AD 1996 m1524
3 AD 1996 m2534
4 AD 1996 m3544
5 AD 1996 m4554
6 AD 1996 m5564
7 AD 1996 m65
8 AD 1996 f014
9 AD 1996 f1524
10 AD 1996 f2534
# i 35,740 more rows
```

Separating

- ▶ 4 columns, but 5 variables, since genage contains both gender and age group. Split that up using separate.
- separate needs 3 things:
 - what to separate (no quotes needed),
 what to separate into (here you do need quotes),

1524

2534

how to split.For "how to split", here "after first character":

A tibble: 35,750 x 5
 iso2 year gender age freq
 <chr> <dbl> <chr> <dbl> 1 AD 1996 m 014 0

2 AD 1996 m

3 AD 1996 m

Tidied tuberculosis data (some)

tb3

```
# A tibble: 35,750 x 5
  iso2 year gender age freq
  <chr> <dbl> <chr> <chr> <dbl>
1 AD
       1996 m
                014
2 AD 1996 m 1524
3 AD 1996 m 2534
4 AD 1996 m 3544
5 AD 1996 m
            4554
6 AD 1996 m
            5564
7 AD 1996 m
                65
8 AD 1996 f
                014
9 AD 1996 f 1524
                2534
10 AD 1996 f
# i 35,740 more rows
```

In practice...

5 AD

▶ instead of doing the pipe one step at a time, you *debug* it one step at a time, and when you have each step working, you use that step's output as input to the next step, thus:

4554

1996 m

Total tuberculosis cases by year (some of the years)

```
tb3 %>%
  filter(between(year, 1991, 1998)) %>%
  group_by(year) %>% summarize(total=sum(freq))
```

```
# A tibble: 8 x 2
  vear total
 <dbl> <dbl>
 1991 544
2 1992 512
3 1993 492
4 1994 750
5 1995 513971
6 1996 635705
7 1997 733204
8 1998 840389
```

Something very interesting happened between 1994 and 1995.

To find out what

Element

- ➤ Column element contains names of two different variables, that should each be in separate column.
- Distinct from eg. m1524 in tuberculosis data, that contained levels of two different factors, handled by separate.
- Untangling names of variables handled by pivot_wider.

Handling element

```
weather %>%
 pivot_longer(d01:d31, names_to="day",
              values_to="temperature",
              values_drop_na = TRUE) %>%
 pivot wider(names from=element,
               values from=temperature)
# A tibble: 355 x 6
  station
              Year Month day
                                tmax
                                      tmin
  <chr>
            <dbl> <chr> <chr> <dbl> <dbl> <dbl>
                          d01 -7.9 -18.6
1 TORONTO CITY 2018 01
2 TORONTO CITY 2018 01
                          d02 -7.1 -12.5
3 TORONTO CITY 2018 01 d03 -5.3 -11.2
4 TORONTO CITY
               2018 01
                          d04 -7.7 -19.7
```

5 TORONTO CITY 2018 01 d05 -14.7 - 20.66 TORONTO CITY 2018 01 d06 -15.4 - 22.37 TORONTO CITY 2018 01 d07 -1 -17.58 TORONTO CITY 3 -1.7 2018 01 d08

Further improvements 1/2

- ▶ We have tidy data now, but can improve things further.
- mutate creates new columns from old (or assign back to change a variable).
- Would like numerical dates. separate works, or pull out number as below.
- select keeps columns (or drops, with minus). Station name has no value to us.

Further improvements 2/2

Final step(s)

- ► Make year-month-day into proper date.
- ► Keep only date, tmax, tmin:

Our tidy data frame

weather_tidy

```
# A tibble: 355 x 3
  date
           tmax tmin
  <date> <dbl> <dbl>
1 2018-01-01 -7.9 -18.6
2 2018-01-02 -7.1 -12.5
3 2018-01-03 -5.3 -11.2
4 2018-01-04 -7.7 -19.7
5 2018-01-05 -14.7 -20.6
6 2018-01-06 -15.4 -22.3
7 2018-01-07 -1 -17.5
8 2018-01-08 3 -1.7
9 2018-01-09 1.6 -0.6
10 2018-01-10 5.9 -1.3
# i 345 more rows
```

Plotting the temperatures

▶ Plot temperature against date joined by lines, but with separate lines for max and min. ggplot requires something like

```
ggplot(..., aes(x = date, y = temperature)) + geom_point() +
  geom_line()
```

only we have two temperatures, one a max and one a min, that we want to keep separate.

- ➤ The trick: combine tmax and tmin together into one column, keeping track of what kind of temp they are. (This actually same format as untidy weather.) Are making weather_tidy untidy for purposes of drawing graph only.
- ► Then can do something like

```
ggplot(d, aes(x = date, y = temperature, colour = maxmin))
+ geom_point() + geom_line()
```

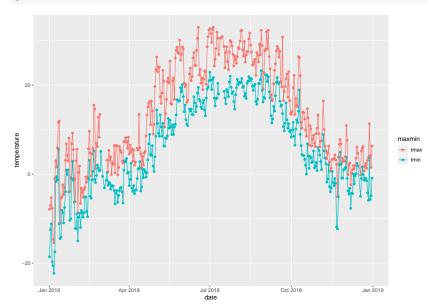

to distinguish max and min on graph.

Setting up plot

- ➤ Since we only need data frame for plot, we can do the column-creation and plot in a pipeline.
- ► For a ggplot in a pipeline, the initial data frame is omitted, because it is whatever came out of the previous step.
- ➤ To make those "one column"s: pivot_longer. I save the graph to show overleaf:

The plot

Summary of tidying "verbs"

Verb	Purpose
pivot_long@ambine columns that measure same thing into one pivot_wideTake column that measures one thing under different conditions and put into multiple columns	
separate	Turn a column that encodes several variables into several columns
unite	Combine several (related) variables into one "combination" variable

pivot_longer and pivot_wider are opposites; separate and unite are opposites.
