library(broom)

## The pigs revisited

Recall pig feed data, after we tidied it:

```
my_url <- "http://ritsokiguess.site/datafiles/pigs2.txt"
pigs <- read_delim(my_url, " ")
pigs</pre>
```

```
# A tibble: 20 x 3
    pig feed weight
  <dbl> <chr> <dbl>
      1 feed1 60.8
      2 feed1 57
3
      3 feed1 65
4
      4 feed1 58.6
5
      5 feed1 61.7
6
      1 feed2 68.7
      2 feed2 67.7
8
      3 feed2 74
      4 feed2
                66.3
```

#### Summaries

4 feed4

```
pigs %>%
 group_by(feed) %>%
 summarize(n = n(), mean_wt = mean(weight),
           sd_wt = sd(weight))
# A tibble: 4 x 4
 feed n mean_wt sd_wt
 <chr> <int> <dbl> <dbl>
1 feed1 5 60.6 3.06
2 feed2 5 69.3 2.93
```

86.2 2.90

3 feed3 5 94.1 3.61 5

## Running through aov and 1m

- ▶ What happens if we run this through 1m rather than aov?
- Recall aov first:

```
pigs.1 <- aov(weight ~ feed, data = pigs)
summary(pigs.1)</pre>
```

```
Df Sum Sq Mean Sq F value Pr(>F)

feed 3 3521 1173.5 119.1 3.72e-11 ***

Residuals 16 158 9.9

---

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '
```

#### and now lm

```
pigs.2 <- lm(weight ~ feed, data = pigs)</pre>
summary(pigs.2)
Call:
lm(formula = weight ~ feed, data = pigs)
Residuals:
  Min
         10 Median 30 Max
-3.900 -2.025 -0.570 1.845 5.000
Coefficients:
          Estimate Std. Error t value Pr(>|t|)
(Intercept) 60.620 1.404 43.190 < 2e-16 ***
feedfeed2 8.680 1.985 4.373 0.000473 ***
feedfeed3 33.480 1.985 16.867 1.30e-11 ***
feedfeed4 25.620 1.985 12.907 7.11e-10 ***
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Residual standard error: 3.138 on 16 degrees of freedom Multiple R-squared: 0.9572, Adjusted R-squared: 0.9491

## Understanding those slopes

- Get one slope for each category of categorical variable feed, except for first.
- feed1 treated as "baseline", others measured relative to that.
- ► Thus prediction for feed 1 is intercept, 60.62 (mean weight for feed 1).
- Prediction for feed 2 is 60.62 + 8.68 = 69.30 (mean weight for feed 2).
- Or, mean weight for feed 2 is 8.68 bigger than for feed 1.
- ▶ Mean weight for feed 3 is 33.48 bigger than for feed 1.
- Slopes can be negative, if mean for a feed had been smaller than for feed 1.

### Reproducing the ANOVA

Pass the fitted model object into anova:

```
anova(pigs.2)
```

Analysis of Variance Table

```
Response: weight

Df Sum Sq Mean Sq F value Pr(>F)

feed 3 3520.5 1173.51 119.14 3.72e-11 ***

Residuals 16 157.6 9.85

---

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

- Same as before.
- But no Tukey this way:

```
TukeyHSD(pigs.2)
```

#### The crickets

- Male crickets rub their wings together to produce a chirping sound.
- Rate of chirping, called "pulse rate", depends on species and possibly on temperature.
- Sample of crickets of two species' pulse rates measured; temperature also recorded.
- Does pulse rate differ for species, especially when temperature accounted for?

## The crickets data

2 exclamationis

7 exclamationis

9 exclamationis

3 niveus

4 niveus 5 niveus

6 niveus

8 niveus

# Fit model with 1m

Can I remove anything? No:

```
drop1(crickets.1, test = "F")
```

Single term deletions

```
Model:
pulse_rate ~ temperature + species
```

Df Sum of Sq RSS AIC F value Pr(>F)
<none> 89.3 38.816

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 '

## The summary

```
summary(crickets.1)
```

```
Call:
lm(formula = pulse_rate ~ temperature + species, data = cr:
```

#### Residuals:

```
Min 1Q Median 3Q Max -3.0128 -1.1296 -0.3912 0.9650 3.7800
```

#### Coefficients:

```
(Intercept) -7.21091 2.55094 -2.827 0.00858 ** temperature 3.60275 0.09729 37.032 < 2e-16 *** speciesniveus -10.06529 0.73526 -13.689 6.27e-14 ***
```

Estimate Std. Error t value Pr(>|t|)

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 '

#### Conclusions

- ➤ Slope for temperature says that increasing temperature by 1 degree increases pulse rate by 3.6 (same for both species)
- ➤ Slope for speciesniveus says that pulse rate for niveus about 10 lower than that for exclamationis at same temperature (latter species is baseline).
- R-squared of almost 0.99 is very high, so that the prediction of pulse rate from species and temperature is very good.

## To end with a graph

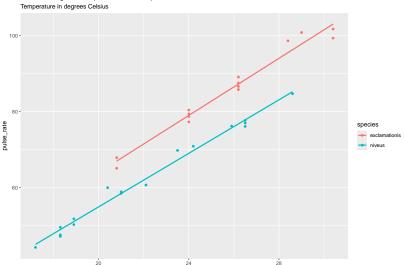

- ► Two quantitative variables and one categorical: scatterplot with categories distinguished by colour.
- This graph seems to need a title, which I define first.

```
t1 <- "Pulse rate against temperature for two species of c:
t2 <- "Temperature in degrees Celsius"
ggplot(crickets, aes(x = temperature, y = pulse_rate,
    colour = species)) +
    geom_point() + geom_smooth(method = "lm", se = FALSE) +
    ggtitle(t1, t2) -> g
```

# The graph

temperature
