Tidying data

Tidying data

- Data rarely come to us as we want to use them.
- Before we can do analysis, typically have organizing to do.
- This is typical of ANOVA-type data, "wide format":

```
pig feed1 feed2 feed3 feed4
  1 60.8
          68.7
                92.6
                     87.9
  2 57.0 67.7
                92.1
                     84.2
  3 65.0 74.0
                90.2
                     83.1
 4 58.6 66.3
               96.5
                     85.7
  5 61.7 69.8 99.1
                     90.3
```

- 20 pigs randomly allocated to one of four feeds. At end of study, weight of each pig is recorded.
- Are any differences in mean weights among the feeds?
- Problem: want all weights in one column, with 2nd column labelling which feed. Untidy!

Tidy and untidy data (Wickham)

- Data set easier to deal with if:
 - each observation is one row
 - each variable is one column
 - each type of observation unit is one table
- Data arranged this way called "tidy"; otherwise called "untidy".
- For the pig data:
 - response variable is weight, but scattered over 4 columns, which are levels of a factor feed.
 - Want all the weights in one column, with a second column feed saying which feed that weight goes with.
 - Then we can run aov.

Packages for this section

```
library(tidyverse)
```

Reading in the pig data

Making it longer

- We wanted all the weights in one column, labelled by which feed they went with.
- This is a very common reorganization, and the magic "verb" is pivot_longer:

```
pigs1 %>% pivot_longer(feed1:feed4, names_to="feed",
                         values_to="weight") -> pigs2
  pigs2
# A tibble: 20 x 3
    pig feed weight
  <dbl> <chr> <dbl>
       1 feed1
                 60.8
2
       1 feed2
                 68.7
3
       1 feed3
                 92.6
4
      1 feed4
                 87.9
5
      2 feed1
                 57
6
       2 feed2
                 67.7
7
       2 feed3
                 92.1
```

```
8
       2 feed4
                  84.2
9
       3 feed1
                  65
10
       3 feed2
                  74
11
       3 feed3
                  90.2
12
       3 feed4
                  83.1
13
       4 feed1
                  58.6
14
       4 feed2
                  66.3
15
       4 feed3
                  96.5
16
       4 feed4
                  85.7
17
       5 feed1
                  61.7
18
       5 feed2
                  69.8
19
       5 feed3
                  99.1
20
       5 feed4
                  90.3
```

Comments

- pigs2 now in "long" format, ready for analysis.
- Anatomy of pivot_longer:
 - columns to combine
 - a name for column that will contain groups ("names")
 - a name for column that will contain measurements ("values")

Identifying the pigs

- Values in pig identify pigs within each group: pig 1 is four different pigs!
- Create unique pig IDs by gluing pig number onto feed:

```
pigs2 %>% mutate(pig_id=str_c(feed, "_", pig)) -> pigs2
  pigs2 %>% slice_sample(n=7)
# A tibble: 7 x 4
   pig feed weight pig_id
 <dbl> <chr>
              <dbl> <chr>
1
     3 feed4
                83.1 feed4_3
2
     3 feed1
                     feed1_3
               65
3
     1 feed4 87.9 feed4_1
               58.6 feed1_4
4
     4 feed1
5
     1 feed1
               60.8 feed1_1
6
     4 feed3
               96.5 feed3 4
     2 feed1
               57
                    feed1_2
```

...and finally, the analysis

• which is just what we saw before:

- The mean weights of pigs on the different feeds are definitely not all equal.
- So we run Tukey to see which ones differ (over).

Tukey

```
TukeyHSD(weight.1)
  Tukey multiple comparisons of means
    95% family-wise confidence level
Fit: aov(formula = weight ~ feed, data = pigs2)
$feed
             diff
                         lwr
                                   upr
                                           p adj
             8.68
feed2-feed1
                    3.001038 14.358962 0.0024000
feed3-feed1 33.48 27.801038 39.158962 0.0000000
feed4-feed1 25.62 19.941038 31.298962 0.0000000
feed3-feed2 24.80 19.121038 30.478962 0.0000000
feed4-feed2 16.94 11.261038 22.618962 0.0000013
feed4-feed3 -7.86 -13.538962 -2.181038 0.0055599
```

All of the feeds differ!

Mean weights by feed

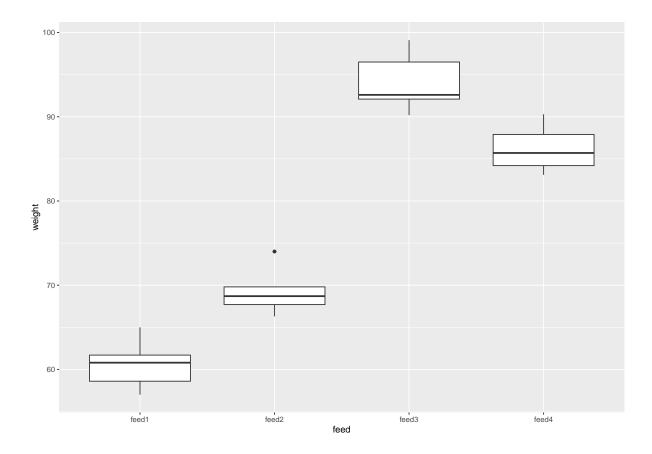

To find the best and worst, get mean weight by feed group. I borrowed an idea from earlier to put the means in descending order:

```
pigs2 %>%
    group_by(feed) %>%
    summarize(mean_weight = mean(weight))%>%
    arrange(desc(mean_weight))
# A tibble: 4 x 2
 feed mean_weight
 <chr>
            <dbl>
1 feed3
              94.1
2 feed4
            86.2
3 feed2
              69.3
4 feed1
              60.6
```

Feed 3 is best, feed 1 worst.

Should we have any concerns about the ANOVA?

```
ggplot(pigs2, aes(x = feed, y = weight)) + geom_boxplot()
```

Comments

- \bullet Feed 2 has an outlier
- But there are only 5 pigs in each group
- The conclusion is so clear that I am OK with this.

Tuberculosis

- The World Health Organization keeps track of number of cases of various diseases, eg. tuberculosis.
- Some data:

```
my_url <- "http://ritsokiguess.site/datafiles/tb.csv"
tb <- read_csv(my_url)</pre>
```

The data (randomly chosen rows)

```
tb %>% slice_sample(n = 10)
# A tibble: 10 x 22
                        m514 m014 m1524 m2534 m3544 m4554 m5564

What we have

- Variables: country (abbreviated), year. Then number of cases for each gender and age group, eg. m1524 is males aged 15-24. Also mu and fu, where age is unknown.
- Lots of missings. Want to get rid of.
- Abbreviations here.

• Code for pivot_longer:

- columns to make longer
- column to contain the names (categorical)
- column to contain the values (quantitative)
- drop missings in the values

Results (some)

Separating

- 4 columns, but 5 variables, since **genage** contains both gender and age group. Split that up using separate.
- separate needs 3 things:
 - what to separate (no quotes needed),
 - what to separate into (here you do need quotes),
 - how to split.
- For "how to split", here "after first character":

```
tb2 %>% separate(genage, c("gender", "age"), 1) -> tb3
```

Tidied tuberculosis data (some)

```
tb3
```

```
# A tibble: 35,750 x 5

In practice...

• instead of doing the pipe one step at a time, you *debug* it one step at a time, and when you have each step working, you use that step's output as input to the next step, thus:

```
# A tibble: 35,750 x 5
          year gender age
                               freq
   <chr> <dbl> <chr>
                       <chr> <dbl>
1 AD
          1996 m
                       014
2 AD
          1996 m
                       1524
                                  0
3 AD
          1996 m
                       2534
                                  0
4 AD
          1996 m
                       3544
                                  4
5 AD
          1996 m
                       4554
                                  1
6 AD
          1996 m
                       5564
                                  0
7 AD
          1996 m
                       65
                                  0
8 AD
          1996 f
                       014
```

```
9 AD 1996 f 1524 1
10 AD 1996 f 2534 1
# i 35,740 more rows
```

- You can split the R code over as many lines as you like, as long as each line is incomplete, so that R knows more is to come.
- I like to put the pipe symbol on the end of the line.

Total tuberculosis cases by year (some of the years)

```
tb3 %>%
    filter(between(year, 1991, 1998)) %>%
    group_by(year) %>% summarize(total=sum(freq))
# A tibble: 8 x 2
  year total
  <dbl>
        <dbl>
  1991
           544
  1992
           512
  1993
           492
  1994
           750
  1995 513971
5
  1996 635705
  1997 733204
7
  1998 840389
```

• Something very interesting happened between 1994 and 1995.

To find out what

• try counting up total cases by country:

```
1 CN
         4065174
2 IN
         3966169
3 ID
         1129015
4 ZA
          900349
5 BD
          758008
6 VN
          709695
7 CD
          603095
8 PH
          490040
9 BR
          440609
10 KE
          431523
# i 203 more rows
```

What years do I have for China?

China started recording in 1995, which is at least part of the problem:

```
tb3 %>% filter(iso2=="CN") %>%
    group_by(year) %>%
    summarize(total=sum(freq))
# A tibble: 14 x 2
   year total
   <dbl> <dbl>
  1995 131194
2
   1996 168270
3
   1997 195895
4
   1998 214404
5
   1999 212258
   2000 213766
7
   2001 212766
   2002 194972
8
9
   2003 267280
10 2004 384886
11 2005 472719
12 2006 468291
13 2007 465877
14 2008 462596
```

First year of recording by country?

• A lot of countries started recording in about 1995, in fact:

```
tb3 %>% group_by(iso2) %>%
    summarize(first_year=min(year)) %>%
    count(first_year)
# A tibble: 14 x 2
   first_year
        <dbl> <int>
 1
         1980
                   2
 2
                   2
         1994
 3
         1995
                 130
 4
         1996
                  31
 5
         1997
                  17
 6
         1998
                   6
7
         1999
                  10
8
         2000
                   4
9
         2001
                   1
                   3
10
         2002
                   2
         2003
11
12
         2004
                   2
13
         2005
                   2
14
         2007
                   1
```

• So the reason for the big jump in cases is that so many countries started recording then, not that there really were more cases.

Some Toronto weather data

```
my_url <-
    "http://ritsokiguess.site/STAC32/toronto_weather.csv"
  weather <- read_csv(my_url)</pre>
  weather

The columns

- Daily weather records for "Toronto City" weather station in 2018:
 - station: identifier for this weather station (always same here)
 - Year, Month
 - element: whether temperature given was daily max or daily min
 - d01, d02,... d31: day of the month from 1st to 31st.

Off we go

Numbers in data frame all temperatures (for different days of the month), so first step is

A tibble: 703 x 6

	${\tt station}$		Year	${\tt Month}$	${\tt element}$	day	temperature
	<chr></chr>		<dbl></dbl>	<chr>></chr>	<chr></chr>	<chr></chr>	<dbl></dbl>
1	TORONTO	CITY	2018	01	tmax	d01	-7.9
2	TORONTO	CITY	2018	01	tmax	d02	-7.1
3	TORONTO	CITY	2018	01	tmax	d03	-5.3
4	TORONTO	CITY	2018	01	tmax	d04	-7.7
5	TORONTO	CITY	2018	01	tmax	d05	-14.7

7	TORONTO	CITY	2018	01	tmax	d07	-1
8	TORONTO	CITY	2018	01	tmax	d08	3

```
9 TORONTO CITY 2018 01 tmax d09 1.6
10 TORONTO CITY 2018 01 tmax d10 5.9
# i 693 more rows
```

Element

- Column element contains names of two different variables, that should each be in separate column.
- \bullet Distinct from eg. m1524 in tuberculosis data, that contained levels of two different factors, handled by separate.
- Untangling names of variables handled by pivot_wider.

Handling element

```
weather %>%
    pivot_longer(d01:d31, names_to="day",
                  values_to="temperature",
                  values_drop_na = TRUE) %>%
    pivot_wider(names_from=element,
                   values_from=temperature)
# A tibble: 355 x 6
   station
                 Year Month day
                                    tmax tmin
   <chr>
                <dbl> <chr> <chr> <dbl> <dbl>

                             d10
# i 345 more rows
```

Further improvements 1/2

• We have tidy data now, but can improve things further.

- mutate creates new columns from old (or assign back to change a variable).
- Would like numerical dates. separate works, or pull out number as below.
- select keeps columns (or drops, with minus). Station name has no value to us.

Further improvements 2/2

```
weather %>%
    pivot_longer(d01:d31, names_to="day",
                 values_to="temperature", values_drop_na = T) %>%
    pivot_wider(names_from=element, values_from=temperature) %>%
    mutate(Day = parse_number(day)) %>%
    select(-station)
# A tibble: 355 x 6
   Year Month day
                      tmax tmin
                                    Day
   <dbl> <chr> <dbl> <dbl> <dbl> <dbl>

                       5.9 - 1.3
10 2018 01
               d10
                                     10
# i 345 more rows
```

Final step(s)

- Make year-month-day into proper date.
- Keep only date, tmax, tmin:

```
mutate(date = as.Date(datestr)) %>%
select(c(date, tmax, tmin)) -> weather_tidy
```

Our tidy data frame

```
weather_tidy
# A tibble: 355 x 3
  date
              tmax tmin
   <date>
             <dbl> <dbl>
1 2018-01-01 -7.9 -18.6
2 2018-01-02 -7.1 -12.5
3 2018-01-03 -5.3 -11.2
4 2018-01-04 -7.7 -19.7
5 2018-01-05 -14.7 -20.6
6 2018-01-06 -15.4 -22.3
7 2018-01-07 -1
8 2018-01-08
                    -1.7
9 2018-01-09
               1.6 -0.6
10 2018-01-10
               5.9 - 1.3
# i 345 more rows
```

Plotting the temperatures

• Plot temperature against date joined by lines, but with separate lines for max and min. ggplot requires something like

```
ggplot(..., aes(x = date, y = temperature)) + geom_point() +
  geom_line()
```

only we have two temperatures, one a max and one a min, that we want to keep separate.

- The trick: combine tmax and tmin together into one column, keeping track of what kind of temp they are. (This actually same format as untidy weather.) Are making weather_tidy untidy for purposes of drawing graph only.
- Then can do something like

```
ggplot(d, aes(x = date, y = temperature, colour = maxmin))
+ geom_point() + geom_line()
```

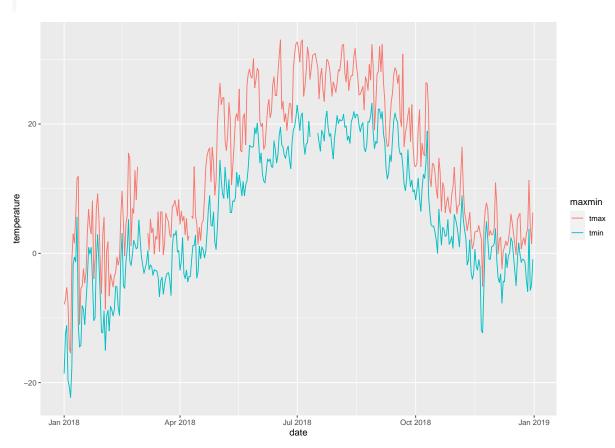

to distinguish max and min on graph.

Setting up plot

- Since we only need data frame for plot, we can do the column-creation and plot in a pipeline.
- For a ggplot in a pipeline, the initial data frame is omitted, because it is whatever came out of the previous step.
- To make those "one column"s: pivot_longer. I save the graph to show overleaf:

The plot

g

Summary of tidying "verbs"

Verb	Purpose
pivot_longer pivot_wider	Combine columns that measure same thing into one Take column that measures one thing under different conditions and put into multiple columns
separate unite	Turn a column that encodes several variables into several columns Combine several (related) variables into one "combination" variable

pivot_longer and pivot_wider are opposites; separate and unite are opposites.
