Discriminant Analysis

Discriminant analysis

- ANOVA and MANOVA: predict a (counted/measured) response from group membership.
- Discriminant analysis: predict group membership based on counted/measured variables.
- Covers same ground as logistic regression (and its variations), but emphasis on classifying observed data into correct groups.
- Does so by searching for linear combination of original variables that best separates data into groups (canonical variables).
- Assumption here that groups are known (for data we have). If trying to "best separate" data into unknown groups, see *cluster analysis*.

Packages

```
library(MASS)
library(tidyverse)
library(ggrepel)
library(ggbiplot)
library(MVTests) # for Box M test
library(conflicted)
conflict_prefer("arrange", "dplyr")
conflict_prefer("summarize", "dplyr")
conflict_prefer("select", "dplyr")
conflict_prefer("filter", "dplyr")
conflict_prefer("mutate", "dplyr")
```

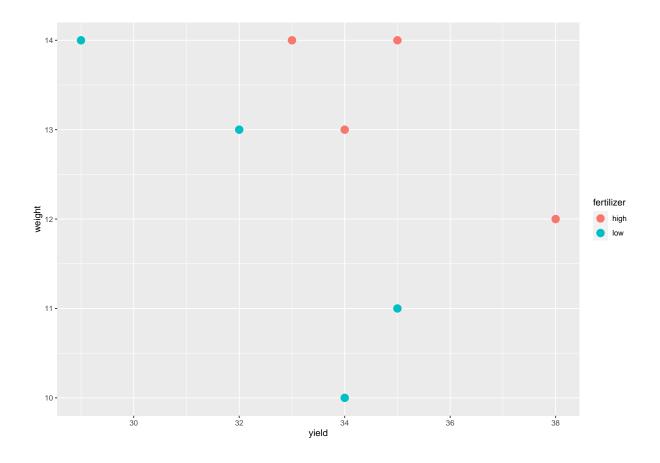

- ggrepel allows labelling points on a plot so they don't overwrite each other.
- ggbiplot uses plyr rather than dplyr, which has functions by similar names.

About select

- Both dplyr (in tidyverse) and MASS have a function called select, and they do different things.
- How do you know which select is going to get called?
- With library, the one loaded *last* is visible, and others are not.
- Thus we can access the select in dplyr but not the one in MASS. If we wanted that one, we'd have to say MASS::select.
- Better: load conflicted package. Any time you load two packages containing functions with same name, you get error and have to choose between them.

Example 1: seed yields and weights

Recall data from MANOVA: needed a multivariate analysis to find difference in seed yield and weight based on whether they were high or low fertilizer.

Basic discriminant analysis

```
hilo.1 <- lda(fertilizer ~ yield + weight, data = hilo)
```

- Uses lda from package MASS.
- "Predicting" group membership from measured variables.

Output

```
hilo.1

Call:
lda(fertilizer ~ yield + weight, data = hilo)

Prior probabilities of groups:
```

```
high low
0.5 0.5

Group means:
yield weight
high 35.0 13.25
low 32.5 12.00

Coefficients of linear discriminants:
LD1
yield -0.7666761
weight -1.2513563
```

Things to take from output

- Group means: high-fertilizer plants have (slightly) higher mean yield and weight than low-fertilizer plants.
- "Coefficients of linear discriminants": LD1, LD2,...are scores constructed from observed variables that best separate the groups.
- For any plant, get LD1 score by taking -0.76 times yield plus -1.25 times weight, add up, standardize.
- the LD1 coefficients are like slopes:
 - if yield higher, LD1 score for a plant lower
 - if weight higher, LD1 score for a plant lower
- High-fertilizer plants have higher yield and weight, thus low (negative) LD1 score. Low-fertilizer plants have low yield and weight, thus high (positive) LD1 score.
- One LD1 score for each observation. Plot with actual groups.

How many linear discriminants?

- Smaller of these:
 - Number of variables
 - Number of groups minus 1
- Seed yield and weight: 2 variables, 2 groups, min(2, 2-1) = 1.

Getting LD scores

Feed output from LDA into predict:

```
p <- predict(hilo.1)</pre>
   hilo.2 <- cbind(hilo, p)
   hilo.2
  fertilizer yield weight class posterior.high posterior.low
                    10 low 2.108619e-05 9.999789e-01 3.0931414
1
        low
               34
                      14 low 1.245320e-03 9.987547e-01 1.9210963
11 low 2.315016e-02 9.768498e-01 1.0751090
2
        low
                29
3
        low
               35
                    13 low 4.579036e-02 9.542096e-01 0.8724245
4
        low
               32
                                 9.817958e-01 1.820422e-02 -1.1456079
       high
               33
                    14 high
               38
                    12 high 9.998195e-01 1.804941e-04 -2.4762756
6
       high
       high
               34
                      13 high
                                 9.089278e-01 9.107216e-02 -0.6609276
       high
               35
                      14 high
                                9.999109e-01 8.914534e-05 -2.6789600
```

LD1 scores in order

Most positive LD1 score is most obviously low fertilizer, most negative is most obviously high:

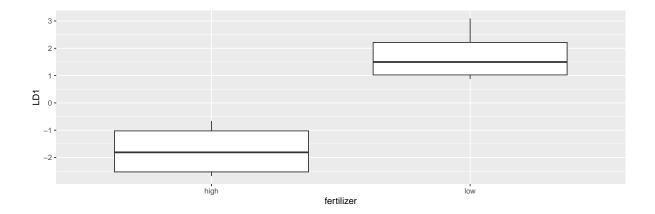

```
hilo.2 %>% select(fertilizer, yield, weight, LD1) %>%
    arrange(desc(LD1))
 fertilizer yield weight
        low
               34
                     10 3.0931414
1
                     14 1.9210963
2
        low
               29
3
        low
               35
                    11 1.0751090
4
        low
               32
                   13 0.8724245
7
       high
               34
                   13 -0.6609276
5
       high
               33
                   14 -1.1456079
       high
               38
                  12 -2.4762756
       high
               35
                    14 -2.6789600
```

High fertilizer have yield and weight high, negative LD1 scores.

Plotting LD1 scores

With one LD score, plot against (true) groups, eg. boxplot:

```
ggplot(hilo.2, aes(x = fertilizer, y = LD1)) + geom_boxplot()
```

What else is in hilo.2?

- class: predicted fertilizer level (based on values of yield and weight).
- posterior: predicted probability of being low or high fertilizer given yield and weight.
- LD1: scores for (each) linear discriminant (here is only LD1) on each observation.

Predictions and predicted groups

...based on yield and weight:

```
hilo.2 %>% select(yield, weight, fertilizer, class)
 yield weight fertilizer class
    34
           10
                     low
    29
           14
2
                     low
                          low
    35
           11
                    low
3
                          low
4
    32
           13
                    low
                          low
5
    33
           14
                   high high
           12
6
    38
                   high high
7
    34
           13
                   high high
    35
           14
                   high high
```

Count up correct and incorrect classification

```
with(hilo.2, table(obs = fertilizer, pred = class))
```

```
pred
obs high low
high 4 0
low 0 4
```

- Each predicted fertilizer level is exactly same as observed one (perfect prediction).
- Table shows no errors: all values on top-left to bottom-right diagonal.

Posterior probabilities

show how clear-cut the classification decisions were:

```
hilo.2 %>%
    mutate(across(starts_with("posterior"), \(p) round(p, 4))) %>%
    select(-LD1)
 fertilizer yield weight class posterior.high posterior.low
1
        low
               34
                     10
                          low
                                      0.0000
                                                    1.0000
2
               29
                                       0.0012
                                                     0.9988
        low
                      14
                           low
3
               35
                     11
                                       0.0232
                                                     0.9768
        low
                           low
4
        low
               32
                      13
                           low
                                       0.0458
                                                     0.9542
       high
               33
                      14 high
                                       0.9818
                                                     0.0182
6
       high
               38
                      12 high
                                       0.9998
                                                     0.0002
                      13 high
7
       high
               34
                                       0.9089
                                                     0.0911
       high
               35
                      14 high
                                       0.9999
                                                     0.0001
```

Only obs. 7 has any doubt: yield low for a high-fertilizer, but high weight makes up for it.

Example 2: the peanuts

```
my_url <- "http://ritsokiguess.site/datafiles/peanuts.txt"</pre>
  peanuts <- read_delim(my_url, " ")</pre>
  peanuts
# A tibble: 12 x 6
    obs location variety

10
     10 8_1
11
     11 8_2
     12 8_2
             200 174. 67.2
```

Discriminant analysis

```
smk 0.1727459 -0.06794271 -0.09386294
w -0.5792456 -0.16300221 0.07341123

Proportion of trace:
   LD1   LD2   LD3
0.8424 0.1317 0.0258
```

Comments

- Now 3 LDs (3 variables, 6 groups, min(3, 6-1) = 3).
- Relationship of LDs to original variables. Look for coeffs far from zero:

```
peanuts.1$scaling
```

```
y 0.4027356 0.02967881 0.18839237
smk 0.1727459 -0.06794271 -0.09386294
w -0.5792456 -0.16300221 0.07341123
```

- high LD1 mainly high y or low w.
- high LD2 mainly low w.
- Proportion of trace values show relative importance of LDs: LD1 much more important than LD2; LD3 worthless.

The predictions and misclassification

```
p <- predict(peanuts.1)</pre>
peanuts.2 <- cbind(peanuts.combo, p)</pre>
with(peanuts.2, table(obs = combo, pred = class))
   pred
    5_1 5_2 6_1 6_2 8_1 8_2

```

Some doubt about which combo each plant belongs in, but not too much. The one misclassified plant was a close call.

Discriminant scores, again

- How are discriminant scores related to original variables?
- Construct data frame with original data and discriminant scores side by side:

```
peanuts.1$scaling
```

```
UD1 LD2 LD3
y 0.4027356 0.02967881 0.18839237
smk 0.1727459 -0.06794271 -0.09386294
w -0.5792456 -0.16300221 0.07341123
```

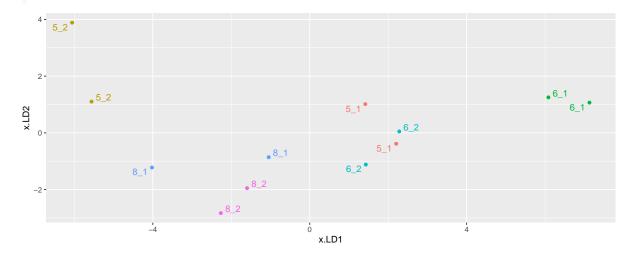

- LD1 positive if y large and/or w small.
- LD2 positive if w small.

Discriminant scores for data

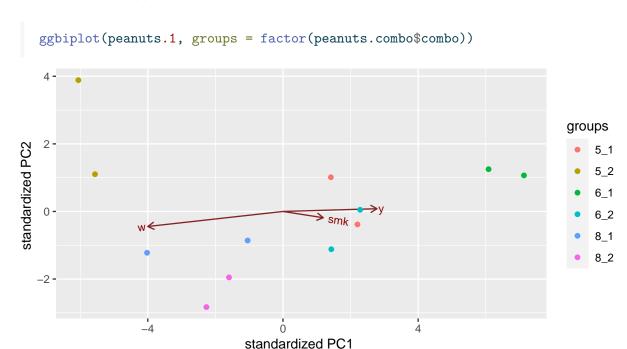

```
peanuts.2 %>% select(y, w, starts_with("x"))
                 x.LD1
                            x.LD2
                                        x.LD3
1 195.3 51.4 1.417354 1.01233393 0.26467918
2 194.3 53.7 2.204444 -0.38421359 -1.12526629
3 189.7 55.5 -5.562217 1.10184441 0.78720394
4 180.4 44.4 -6.056558 3.88530191 -0.05263163
5 203.0 49.8 6.084370 1.25027629 1.25054957
6 195.9 45.8 7.131192 1.06649258 -1.24422021
7 202.7 60.4 1.430084 -1.11831802 1.09926555
8 197.6 54.1 2.282572 0.04938762 0.07958437
9 193.5 57.8 -1.045438 -0.85884902 -0.67463274
10 187.0 58.6 -4.022969 -1.22292871 -1.89677191
11 201.5 65.0 -1.596806 -1.95130266 1.14518230
12 200.0 67.2 -2.266028 -2.83002474 0.36705787
```

- Obs. 5 and 6 have most positive LD1: large y, small w.
- Obs. 4 has most positive LD2: small w.

Plot LD1 vs. LD2, labelling by combo

"Bi-plot" from ggbiplot

Installing ggbiplot

- ggbiplot not on CRAN, so usual install.packages will not work.
- Install package devtools first (once):

```
install.packages("devtools")
```

• Then install ggbiplot (once):

```
library(devtools)
install_github("vqv/ggbiplot")
```

Cross-validation

- So far, have predicted group membership from same data used to form the groups dishonest!
- Better: *cross-validation*: form groups from all observations *except one*, then predict group membership for that left-out observation.

- No longer cheating!
- Illustrate with peanuts data again.

Misclassifications

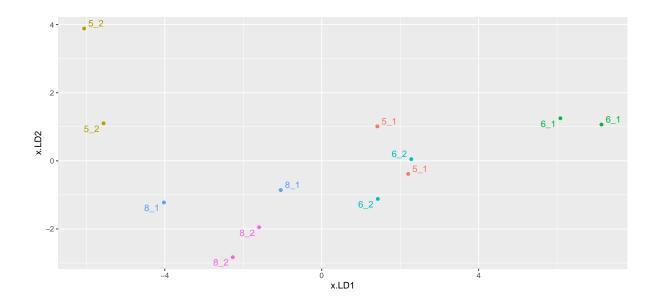

• Fitting and prediction all in one go:

```
pred
obs 5_1 5_2 6_1 6_2 8_1 8_2
5_1 0 0 0 0 2 0 0
5_2 0 1 0 0 1 0
6_1 0 0 2 0 0
6_2 1 0 0 1 0 0
8_1 0 1 0 0 0 0
2
```

• Some more misclassification this time.

Repeat of LD plot

Why more misclassification?

- When predicting group membership for one observation, only uses the *other one* in that group.
- So if two in a pair are far apart, or if two groups overlap, great potential for misclassification.
- Groups 5_1 and 6_2 overlap.
- 5_2 closest to 8_1s looks more like an 8_1 than a 5_2 (other one far away).
- 8_1s relatively far apart and close to other things, so one appears to be a 5_2 and the other an 8_2.

Example 3: professions and leisure activities

- 15 individuals from three different professions (politicians, administrators and belly dancers) each participate in four different leisure activities: reading, dancing, TV watching and skiing. After each activity they rate it on a 0–10 scale.
- How can we best use the scores on the activities to predict a person's profession?
- Or, what combination(s) of scores best separate data into profession groups?

The data

```
my_url <- "http://ritsokiguess.site/datafiles/profile.txt"
active <- read_delim(my_url, " ")
active</pre>
```

A tibble: 15 x 5

job	reading	dance	tv	ski

2 bellydancer	8	9	5	7
3 bellydancer	5	10	5	8
4 bellydancer	6	10	6	8
5 bellydancer	7	8	7	9
6 politician	4	4	4	4
7 politician	6	4	5	3

```
8 politician 5 5 6 6 9 politician 6 6 6 7 10 politician 4 5 6 5 11 admin 3 1 1 2 12 admin 5 3 1 5 13 admin 4 2 2 5 5 14 admin 7 1 2 4 15 admin 6 3 3 3
```

Discriminant analysis

Comments

- Two discriminants, first fair bit more important than second.
- LD1 depends (negatively) most on dance, a bit on tv.
- LD2 depends mostly (negatively) on tv.

Misclassification

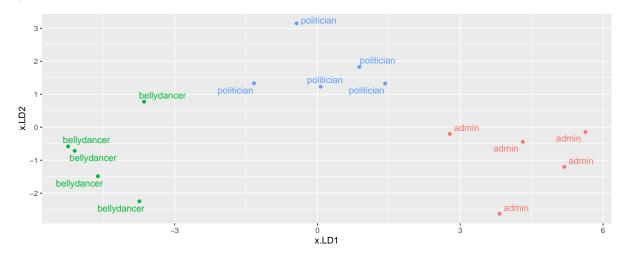

```
p <- predict(active.1)
active.2 <- cbind(active, p)
with(active.2, table(obs = job, pred = class))</pre>
```

pred obs admin bellydancer politician admin 5 0 0 bellydancer 0 5 0 politician 0 5

Everyone correctly classified.

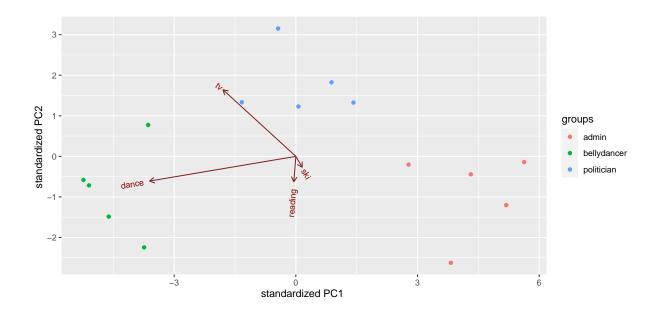

Plotting LDs

```
g <- ggplot(active.2, aes(x = x.LD1, y = x.LD2, colour = job, label = job)) +
   geom_point() + geom_text_repel() + guides(colour = "none")
g</pre>
```

Biplot

```
ggbiplot(active.1, groups = active$job)
```

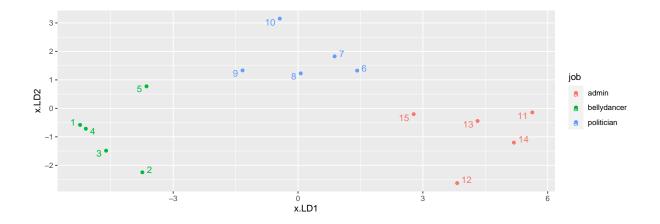

Comments on plot

- Groups well separated: belly dancers top left, administrators top right, politicians lower middle.
- Bellydancers most negative on LD1: like dancing most.
- Administrators most positive on LD1: like dancing least.
- Politicians most negative on LD2: like TV-watching most.

Plotting individual persons

Make label be identifier of person. Now need legend:

Posterior probabilities

```
active.2 %>% mutate(across(starts_with("posterior"), \(p) round(p, 3))) %>%
    select(job, class, starts_with("posterior"))
```

	job	class	posterior.admin	posterior.bellydancer
1	•	bellydancer	0.000	1.000
2	bellydancer	bellydancer	0.000	1.000
3		bellydancer	0.000	1.000
4	bellydancer	bellydancer	0.000	1.000
5	bellydancer	bellydancer	0.000	0.997
6	politician	politician	0.003	0.000
7	politician	politician	0.000	0.000
8	politician	politician	0.000	0.000
9	politician	politician	0.000	0.002
10	politician	politician	0.000	0.000
11	admin	admin	1.000	0.000
12	admin	admin	1.000	0.000
13	admin	admin	1.000	0.000
14	admin	admin	1.000	0.000
15	admin	admin	0.982	0.000
	posterior.po	olitician		
1		0.000		
2		0.000		
3		0.000		
4		0.000		
5		0.003		
6		0.997		
7		1.000		
8		1.000		
9		0.998		
10		1.000		
11		0.000		
12		0.000		
13		0.000		
14		0.000		
15		0.018		

Not much doubt.

Cross-validating the jobs-activities data

Recall: no need for predict:

```
p <- lda(job ~ reading + dance + tv + ski, data = active, CV = TRUE)
active.3 <- cbind(active, class = p$class, posterior = p$posterior)
with(active.3, table(obs = job, pred = class))</pre>
```

]	pred		
obs	admin	bellydancer	politician
admin	5	0	0
bellydancer	0	4	1
politician	0	0	5

This time one of the bellydancers was classified as a politician.

and look at the posterior probabilities

```
active.3 %>%
    mutate(across(starts_with("posterior"), \(p) round(p, 3))) %>%
     select(job, class, starts_with("post"))
                   class posterior.admin posterior.bellydancer
          job
                            0.000

Comments

- Bellydancer was "definitely" a politician!
- One of the administrators might have been a politician too.

Why did things get misclassified?

Go back to plot of discriminant scores:

- one bellydancer much closer to the politicians,
- one administrator a bit closer to the politicians.

Example 4: remote-sensing data

- View 25 crops from air, measure 4 variables x1-x4.
- Go back and record what each crop was.
- Can we use the 4 variables to distinguish crops?

The data

```
my_url <- "http://ritsokiguess.site/datafiles/remote-sensing.txt"
crops <- read_table(my_url)
crops %>% print(n = 25)
```

```
# A tibble: 25 x 6
   crop x1
                        x2
                              xЗ
                                     x4 cr

```

Discriminant analysis

Assessing

- 3 LDs (four variables, four groups).
- 1st two important.
- LD1 mostly x1 (minus)
- LD2 x3 (minus)

Predictions

• Thus:

```
p <- predict(crops.1)</pre>
   crops.2 <- cbind(crops, p)</pre>
   with(crops.2, table(obs = crop, pred = class))
             pred
obs
              Corn Cotton Soybeans Sugarbeets
  {\tt Corn}
                 6
                         0
                                   1
                                                0
                 0
                                    2
  {\tt Cotton}
                          4
                                                0
  Soybeans
                 2
                          0
                                    3
                                                1
                  0
                         0
                                    3
  Sugarbeets
```

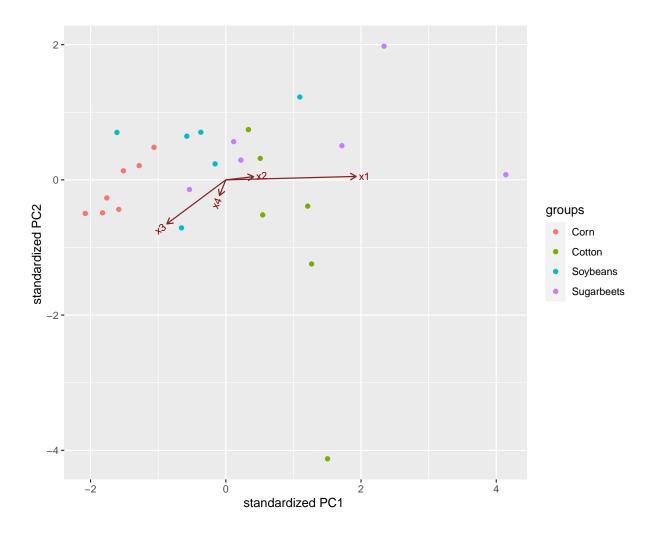

• Not very good, eg. only half the Soybeans and Sugarbeets classified correctly.

Plotting the LDs

Corn (red) mostly left, cotton (green) sort of right, soybeans and sugarbeets (blue and purple) mixed up.

Biplot

```
ggbiplot(crops.1, groups = crops$crop)
```

Comments

- Corn low on LD1 (left), hence low on x1
- Cotton tends to be high on LD1 (high x1)
- one cotton very low on LD2 (high x3?)
- Rather mixed up.

Posterior probs (some)

```
crops.2 %>% mutate(across(starts_with("posterior"), \(p) round(p, 3))) %>%
     filter(crop != class) %>%
     select(crop, class, starts_with("posterior"))
                 class posterior.Corn posterior.Cotton posterior.Soybeans
        crop

```

Comments

- These were the misclassified ones, but the posterior probability of being correct was not usually too low.
- The correctly-classified ones are not very clear-cut either.

MANOVA

Began discriminant analysis as a followup to MANOVA. Do our variables significantly separate the crops?

```
response <- with(crops, cbind(x1, x2, x3, x4))
crops.manova <- manova(response ~ crop, data = crops)
summary(crops.manova)

Df Pillai approx F num Df den Df Pr(>F)
crop 3 0.9113 2.1815 12 60 0.02416 *
Residuals 21
```

```
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Box's M test

We should also run Box's M test to check for equal variance of each variable across crops:

```
summary(BoxM(response, crops$crop))
Box's M Test
```

Chi-Squared Value = 69.42634 , df = 30 and p-value: 5.79e-05

- The P-value for the M test is smaller even than our guideline of 0.001. So we should not take the MANOVA seriously.
- Apparently at least one of the crops differs (in means) from the others. So it is worth doing this analysis.
- We did this the wrong way around, though!

The right way around

- First, do a MANOVA to see whether any of the groups differ significantly on any of the variables.
- Check that the MANOVA is believable by using Box's M test.
- If the MANOVA is significant, do a discriminant analysis in the hopes of understanding how the groups are different.
- For remote-sensing data (without Clover):
 - LD1 a fair bit more important than LD2 (definitely ignore LD3).
 - LD1 depends mostly on x1, on which Cotton was high and Corn was low.
- Discriminant analysis in MANOVA plays the same kind of role that Tukey does in ANOVA.
